

Dependencies in Syntax and Phonology: A Computational Comparison

Thomas Graf (and Jeff Heinz, sorta)

`mail@thomasgraf.net`

`http://thomasgraf.net`

Department of Linguistics
Stony Brook University

NECPHON
November 15 2014

Today's Topic

The Received View on Syntax and Phonology

- Little cross-talk between syntax and phonology
- Properties of one supposedly have no bearing on the other
- Huge difference with respect to weak generative capacity

Counter Position

- Computationally, phonology and syntax are very similar.
- Over linguistically plausible models, both rely on dependencies of the same computational complexity.
- Main difference is data structures: **strings** versus **trees**

Today's Topic

The Received View on Syntax and Phonology

- Little cross-talk between syntax and phonology
- Properties of one supposedly have no bearing on the other
- Huge difference with respect to weak generative capacity

Counter Position

- Computationally, phonology and syntax are very similar.
- Over linguistically plausible models, both rely on dependencies of the same computational complexity.
- Main difference is data structures: **strings** versus **trees**

Outline

- 2 Phonology is Tier-Based Strictly Local
 - n -gram Grammars
 - Tiers for Non-Local Dependencies
- 3 A Closer Look at Syntax
 - Minimalist Grammars
 - A Quick Example
 - The Shortest Move Constraint
- 4 Underlyingly, Syntax is Tier-Based Strictly Local
 - MGs as Regular Derivation Tree Languages
 - Merge is Strictly Local
 - Move is Tier-Based Strictly Local

Linguistics: Syntax and Phonology are Unrelated

• Different Frameworks

Aspects ⇔ SPE

GB ⇔ Autosegmental/GP

Minimalism ⇔ OT

• Empirical Separation

- What is the syntactic analog of umlaut or final devoicing?
- What is the phonological analog of passive or the Person Case Constraint?
- Cognitive impairments often impact only one of the two.

Language as Sets

Formally, a language is simply

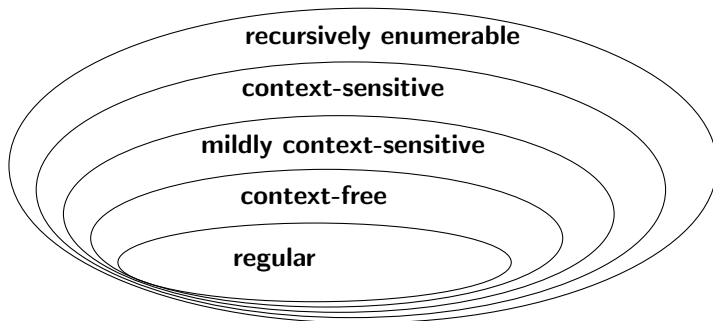

a set of objects of a specific type:

- **graph**: structure of connected nodes
flow chart, street network, Wikipedia, internet, video game AI
- **tree**: connected graph where every node is reachable from at most one node
family tree, hard drive layout, XML file
- **string**: sequence of nodes
telephone number, Python program, human genome, Shakespeare's oeuvre

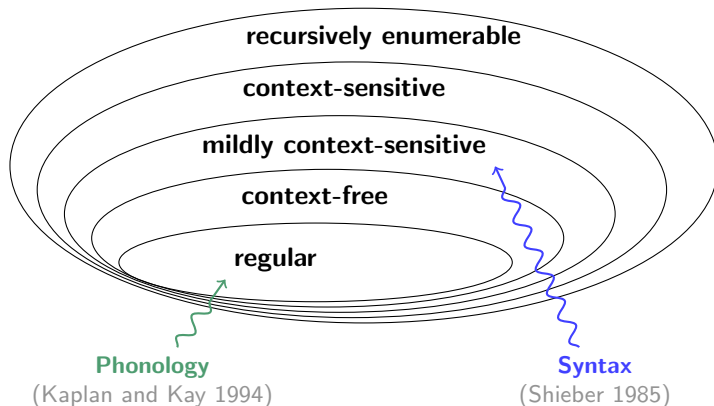

The Chomsky Hierarchy of String Languages

- The perceivable output of language is strings (sequences of sound waves, words, sentences).
- The complexity of string languages is measured by the (extended) **Chomsky hierarchy**. (Chomsky 1956, 1959)

The Chomsky Hierarchy of String Languages

- The perceivable output of language is strings (sequences of sound waves, words, sentences).
- The complexity of string languages is measured by the (extended) **Chomsky hierarchy**. (Chomsky 1956, 1959)

Pinpointing Phonology in the Chomsky Hierarchy

- Regular languages are too powerful for phonology.
- Jeff Heinz has argued that phonology can be described by a natural generalization of n -gram grammars. (Heinz et al. 2011)
- **Idea:** non-local dependencies are **local on phonological tiers**

(Negative) Bigram Grammars

- Suppose we have a fixed alphabet Σ (e.g. sounds of English).
- A bigram is a sequence **ab** s.t. **a**, **b** $\in \Sigma$.
- A **bigram grammar** G is a finite set of bigrams.
- G generates the largest language of strings such that no string contains any bigrams of G as a substring
- Intuition: **bigrams are hard, local constraints**

Example

Rewrite rule	Constraint	Bigrams
n \rightarrow m b	* nb	nb
z \rightarrow s \$	* z\$	z\$
[-voice] \rightarrow \emptyset \$	* [-voice]\$	s\$, θ\$, f\$, ...

(Negative) Bigram Grammars

- Suppose we have a fixed alphabet Σ (e.g. sounds of English).
- A bigram is a sequence **ab** s.t. **a**, **b** $\in \Sigma$.
- A **bigram grammar** G is a finite set of bigrams.
- G generates the largest language of strings such that no string contains any bigrams of G as a substring
- Intuition: **bigrams are hard, local constraints**

Example

Rewrite rule	Constraint	Bigrams
n \rightarrow m b	* nb	nb
z \rightarrow s \$	* z\$	z\$
[-voice] \rightarrow \emptyset \$	* [-voice]\$	s\$, θ\$, f\$, ...

Tiers for Long-Distance Dependencies

- We can move to 3-grams, 4-grams, \dots n -grams in order to regulate less local processes (e.g. umlaut).
- **Problem:** Still limited to locality domain of size n
 \Rightarrow unbounded processes cannot be captured
- **Solution:** segments can be on multiple tiers

Tier-Based Bigram Grammar

- Let $T \subseteq \Sigma$ be a tier alphabet.
- A **tier-based bigram grammar** G is a pair of finite sets of bigrams over Σ and T , respectively.
- G generates s iff
 - s has no Σ -bigram as a substring,
 - the restriction of s to elements of T has no T -bigram as a substring.

Tiers for Long-Distance Dependencies

- We can move to 3-grams, 4-grams, ... n -grams in order to regulate less local processes (e.g. umlaut).
- **Problem:** Still limited to locality domain of size n
 \Rightarrow unbounded processes cannot be captured
- **Solution:** segments can be on multiple tiers

Tier-Based Bigram Grammar

- Let $T \subseteq \Sigma$ be a tier alphabet.
- A **tier-based bigram grammar** G is a pair of finite sets of bigrams over Σ and T , respectively.
- G generates s iff
 - s has no Σ -bigram as a substring,
 - the restriction of s to elements of T has no T -bigram as a substring.

Example: Sibilant Harmony

Rewrite rule

s → ∫ | ∫ . . . -

Constraint

*∫ . . . **s**

Tier-Bigram

∫**s**

T-Tier:

\$ ∫ **s** \$

| | | |

Σ-Tier:

\$ e ∫ i s i \$

Example: Primary Stress Assignment

- Every word must have exactly one primary stress.
- Let T be the set of symbols with primary stress.
- Then we need the following T -bigrams:
 - \$\$ “at least one primary stress”
 - ab “not more than one primary stress” (for all $a, b \in T$)

Stress Missing

\$						\$
\$	e	ɪ	s	i		\$

Too Many Stresses

\$	'e		'i			\$
\$	'e	ɪ	'i	s	i	\$

Just Right

\$	'e					\$
\$	'e	ɪ	s	i		\$

Phonology is Subregular

- Tier-based n -gram grammars generate only a subclass of the regular languages.
- Only a few known phenomena might not to be tier-local, but the data is unclear (e.g. primary stress assignment in Cairene Arabic; Graf 2010)
- Hence **phonology is subregular**.
- **Core insights**
 - Most phonological dependencies are local.
 - Non-local dependencies are local between the elements of the relevant type (\approx tier).

A Closer Look at Syntax

The MCS-result treats syntactic patterns as string dependencies.
But **syntacticians work with trees**, not strings.

Minimalist Grammars

- **Minimalism** is the dominant syntactic theory. (Chomsky 1995)
- Can Minimalism change the computational picture of syntax? Maybe, but first we need a precise specification.
- **Minimalist grammars** are such a formalization, developed by Ed Stabler. (Stabler 1997)
- They are expressive enough for syntax.

Syntax as Chemistry of Language

Minimalist grammars treat syntax like chemistry.

Chemistry	Syntax
atoms	words
electrons	features
molecules	sentences
stable	grammatical
unstable	ungrammatical

- Every word is a collection of features.
- Every feature has either positive or negative polarity.
- Features of opposite polarity annihilate each other.
- Feature annihilation drives the structure-building operations **Merge** and **Move**.

Syntax as Chemistry of Language

Minimalist grammars treat syntax like chemistry.

Chemistry	Syntax
atoms	words
electrons	features
molecules	sentences
stable	grammatical
unstable	ungrammatical

- Every word is a collection of features.
- Every feature has either positive or negative polarity.
- Features of opposite polarity annihilate each other.
- Feature annihilation drives the structure-building operations **Merge** and **Move**.

Merge: Example 1

Assembling $[_{DP} \text{ the men}]$

$$\frac{\text{the}}{N^+ D^-} \quad \frac{\text{men}}{N^-}$$

- Features of opposite polarities annihilate
- Annihilation triggers Merge, which builds structure on top

Merge: Example 1

Assembling $[_{DP} \text{ the men}]$

$$\frac{\text{the}}{N^+ D^-} \quad \frac{\text{men}}{N^-}$$

- Features of opposite polarities annihilate
- Annihilation triggers Merge, which builds structure on top

Merge: Example 1

Assembling $[_{DP} \text{ the men}]$

$$\frac{\text{the}}{N^+ D^-} \quad \frac{\text{men}}{N^-}$$

- Features of opposite polarities annihilate
- Annihilation triggers Merge, which builds structure on top

Merge: Example 1

Assembling [_{DP} the men]

- Features of opposite polarities annihilate
- Annihilation triggers Merge, which builds structure on top

Merge: Example 1

Assembling [DP the men]

- Features of opposite polarities annihilate
- Annihilation triggers Merge, which builds structure on top

Merge: Example 2

Assembling [_{VP} the men like which men]

the	men	like	which	men
N ⁺ D ⁻	N ⁻	D ⁺ D ⁺ V ⁻	N ⁺ D ⁻	N ⁻

- *the* and *men* merged as before
- same steps for *which men*
- *like* merged with *which men*
- *like* merged with *the men*

Merge: Example 2

Assembling [_{VP} the men like which men]

the	men	like	which	men
N ⁺ D ⁻	N ⁻	D ⁺ D ⁺ V ⁻	N ⁺ D ⁻	N ⁻

- *the* and *men* merged as before
- same steps for *which men*
- *like* merged with *which men*
- *like* merged with *the men*

Merge: Example 2

Assembling [_{VP} the men like which men]

- *the* and *men* merged as before
- same steps for *which men*
- *like* merged with *which men*
- *like* merged with *the men*

Merge: Example 2

Assembling [_{VP} the men like which men]

- *the* and *men* merged as before
- same steps for *which men*
- *like* merged with *which men*
- *like* merged with *the men*

Merge: Example 2

Assembling [_{VP} the men like which men]

- *the* and *men* merged as before
- same steps for *which men*
- *like* merged with *which men*
- *like* merged with *the men*

Merge: Example 2

Assembling [_{VP} the men like which men]

- *the* and *men* merged as before
- same steps for *which men*
- *like* merged with *which men*
- *like* merged with *the men*

Merge: Example 2

Assembling [_{VP} the men like which men]

- *the* and *men* merged as before
- same steps for *which men*
- *like* merged with *which men*
- *like* merged with *the men*

Merge: Example 2

Assembling [_{VP} the men like which men]

- *the* and *men* merged as before
- same steps for *which men*
- *like* merged with *which men*
- *like* merged with *the men*

Merge: Example 2

Assembling [_{VP} the men like which men]

- *the* and *men* merged as before
- same steps for *which men*
- *like* merged with *which men*
- *like* merged with *the men*

Merge: Example 2 [cont.]

Move

Assembling “which men do the men like?”

- Merge *do*
- Move triggered by features of opposite polarity

Move

Assembling “which men do the men like?”

- Merge *do*
- Move triggered by features of opposite polarity

Move

Assembling “which men do the men like?”

- Merge *do*
- Move triggered by features of opposite polarity

Move

Assembling “which men do the men like?”

- Merge *do*
- Move triggered by features of opposite polarity

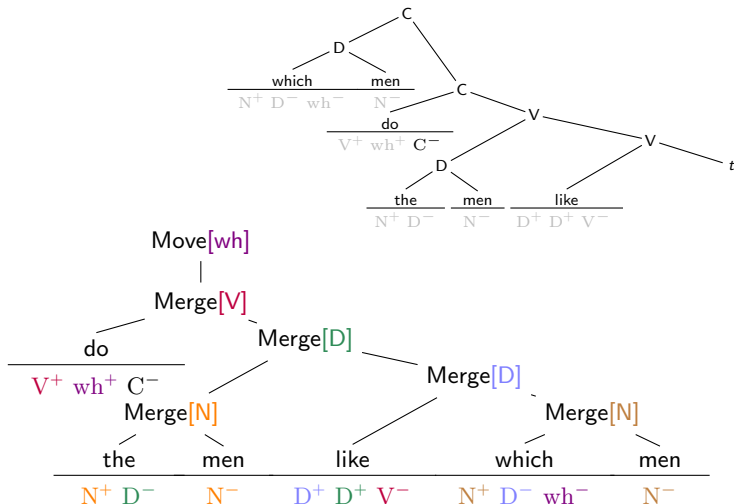

Move

Assembling “which men do the men like?”

- Merge *do*
- Move triggered by features of opposite polarity

Derivation Trees with Move

An Important Restriction on MGs

In order to ensure that MGs generate only MCS-languages, movement must be restricted.

Shortest Move Constraint (SMC)

If two lexical items in a tree both have a negative Move feature as their first currently unchecked feature, then these features must be distinct.

An Important Restriction on MGs

In order to ensure that MGs generate only MCS-languages, movement must be restricted.

Shortest Move Constraint (SMC)

If two lexical items in a tree both have a negative Move feature as their first currently unchecked feature, then these features must be distinct.

An Important Restriction on MGs

Shortest Move Constraint (SMC)

If two lexical items in a tree both have a negative Move feature as their first currently unchecked feature, then these features must be distinct.

An Important Restriction on MGs

In order to ensure that MGs generate only MCS-languages, movement must be restricted.

Shortest Move Constraint (SMC)

If two lexical items in a tree both have a negative Move feature as their first currently unchecked feature, then these features must be distinct.

What's the Point?

- Sentences aren't just strings, they contain hidden structure.
- Syntacticians usually look at the tree structure that is built by the operations Merge and Move.
- **But:** the history of how such a structure is built is also a tree
⇒ **phrase structure trees** and **derivation trees** as two possible views of tree-based syntax

The Complexity of MGs

- Since syntax is described by trees, we should look at tree languages instead of string languages.
- Every MG can be identified with
 - its set of phrase structure trees, or
 - its set of derivation trees
- The set of phrase structure trees is not regular.
(Doner 1970; Thatcher 1967)
- But the set of derivation trees is regular.
(Michaelis 2001; Kobele et al. 2007; Graf 2012)

The Big Question

Are MG derivation tree languages tier-based strictly local?

The Complexity of MGs

- Since syntax is described by trees, we should look at tree languages instead of string languages.
- Every MG can be identified with
 - its set of phrase structure trees, or
 - its set of derivation trees
- The set of phrase structure trees is not regular.
(Doner 1970; Thatcher 1967)
- But the set of derivation trees is regular.
(Michaelis 2001; Kobele et al. 2007; Graf 2012)

The Big Question

Are MG derivation tree languages tier-based strictly local?

Tree n -gram Grammars

- We need to lift n -grams from strings to trees.
- Instead of strings of length n , use subtrees of depth n .
- Each subtree encodes a constraint on the derivation.

Example: Bigram template for merging only matching LIs

where **head** and **arg** lack matching Merge features

Merge is Strictly Local

- An LI's Merge features are checked by its arguments.
- The distance between a head and the head of its argument is bounded by some factor k (which depends on how many arguments a head may take).
- Hence Merge dependencies are n -local for some fixed n .
- It follows that **Merge is tier-based strictly local**.

Constraints on Move

Suppose our MG is in **single movement normal form**.

Occurrence

Given lexical item l with negative Move feature f^- , a node m is an **occurrence** of l iff m is the lowest node dominating l that can check f^- .

Movement Dependencies

- **Move**

Every lexical item with a negative Move feature has exactly one occurrence.

- **SMC**

Every Move node is an occurrence of exactly one lexical item.

Tiers for Movement

- There is no upper bound on the distance between a lexical item and its occurrence.
- Consequently, **Move dependencies are not strictly local.**
- What if every movement type (wh, topic, ...) induces its own tier? Would that make Move dependencies local?

Tiers for Movement

- There is no upper bound on the distance between a lexical item and its occurrence.
- Consequently, **Move dependencies are not strictly local**.
- What if every movement type (wh, topic, ...) induces its own tier? Would that make Move dependencies local?

Tiers for Movement

- There is no upper bound on the distance between a lexical item and its occurrence.
- Consequently, **Move dependencies are not strictly local**.
- What if every movement type (wh, topic, ...) induces its own tier? Would that make Move dependencies local?

Tiers for Movement

- There is no upper bound on the distance between a lexical item and its occurrence.
- Consequently, **Move dependencies are not strictly local**.
- What if every movement type (wh, topic, ...) induces its own tier? Would that make Move dependencies local?

Tree Bigrams for Move

Move amounts to the following constraints over each tier:

- **Move**

Every lexical item has a mother labeled Move.

- **SMC**

Among the daughters of a Move node there exists exactly one that is a lexical item.

Tree Bigram Templates

Move1

\$

LI

Move2

LI

┌───┴───┐
: ... LI ... :
└───┬───┘

SMC

Move

┌───┴───┐
: ... LI ... LI ... :
└───┬───┘

The Problem With Our Bigrams

- No limit on number of daughters per Move node in tier
⇒ **Move2** and **SMC** correspond to infinitely many bigrams
- But a bigram grammar must be finite!

A Hint from Multidimensional Trees

- We think of trees as nodes ordered by dominance and precedence.
- Jim Rogers (2003) formalizes trees as strings (sequences of siblings) related by dominance.
- Analogously, a tree-tier may consist of **string-tiers related by dominance!**

Checking the Example Derivation

General Verification Procedure

- Take derivation and project Move tiers.
- In every Move tier, project LI-tiers.
- For every node, build a bigram consisting of the node and the LI-tier of its daughter string.

From Templates to Tree Bigrams with String Tiers

- Each string of siblings is given an LI-tier.
- The tree bigrams only reference the LI-tier.

Old Tree Bigram Templates

Move2

SMC1

SMC2

Conclusion

- Syntax and phonology look very different, but computationally they are very similar.
- Phonology is tier-based strictly local over strings.
- Syntax is tier-based strictly local over derivation trees.
- **Intuition**
 - Non-local dependencies are not particularly complex.
 - They are **local over some relativization domain**.
